Unique

- Charcot-Marie-Tooth disease (CMT) is an inherited neuromuscular disease caused by mutations in genes that produce proteins involved in the structure and function of either the myelin sheath or the peripheral nerve axon.1
- The slow degeneration of the nerves results in a decreased ability to communicate with their distant targets leading to symmetric distal muscle atrophy and weakness, hand and foot deformities, and sensory loss.2-3
- There is currently no treatment that reverses or stops the progression of the disease; however, there are physical therapy (PT) interventions that reduce the level of disability in individuals with CMT. Research has shown that interval and resistance exercise can improve functional capacity, strength and activities of daily living (ADLs) in people with CMT.7-8
- Myocardial infarction (MI) is often a result of coronary artery disease (CAD), which has an incidence rate of 34.6% in men over 80.10 Immediate exercise interventions in the acute care setting following an MI have shown to positively impact a patient’s functional capacity and quality of life.11
- While rehabilitation practices for CMT and MI have been described separately, there is a paucity of research investigating the optimal physical therapy (PT) interventions for patients who have both health conditions concurrently.

Purpose

To describe a progressive PT plan of care for a patient with CMT following an acute myocardial infarction (MI) in the acute and sub-acute care settings.

Foundation

- Bed rest remains a common treatment for managing acute illness even while its efficacy is not supported by the literature.12 It is well documented that prolonged bed rest causes profound deconditioning of multiple body systems.13-15
- Research has suggested that physical exercise and early mobilization may help reduce the consequences of bed rest and improve long-term outcomes.16
- A progressive and structured PT plan of care for a person with CMT following a complicated MI was hypothesized to improve function and long-term outcomes.

Case Description

- 60-year-old male with past medical history CMT, CAD status-post three-vessel coronary artery bypass grafting 10 years prior, hypertension, hyperlipidemia.
- Admitted to the ER with an MI that required emergent left heart catheterization.
- During the procedure, the patient went into acute respiratory failure requiring intubation.
- He spent 6 days on complete bed rest while intubated in the ICU.
- Initial PT evaluation on day 7 revealed significantly decreased strength, endurance, balance and chronically impaired hand and foot function.
- He received ~30 minutes/day of acute care PT for four days, as well as OT and SLP.
- He was discharged to the hospital’s Inpatient Rehab facility and received two daily one-hour sessions of PT for five days, as well as daily OT and SLP.
- Prior to admission, the patient was independent with functional mobility using bilateral ankle-foot orthoses and two trekking poles for long-distance ambulation and was independent with all ADLs.

Observations

- Patient was successfully discharged home after 9 days of progressive PT despite the fact that the patient initially required minimal assistance for bed mobility, maximal assistance for transfers, and maximal assistance to ambulate 2 feet using a walker.
- He increased his strength, activity tolerance, balance, and independence with all functional mobility.
- Gait improvements were demonstrated and included more upright posture, increased step length, faster gait speed and improved stability, as demonstrated by graduation from front-wheel walker to bilateral trekking poles.

Progression of Required Assistance with Functional Mobility Across Episode of Care

Progressions:

1. Standing Balance: P00 to 739
2. Sitting Balance: Fair to Good
3. Transfers: Minimum Assistance to Modified Independent
4. Bed Mobility: Minimal Assistance to Supervision
5. Gait: Independent to Modified Independent
6. Functional Mobility Training: Early strengthening
7. Stair Training
8. Therapeutic Exercise for Strengthening

Conclusions

CMT and MI in combination can be especially debilitating. An aggressive rehabilitation course that promoted balance, functional mobility and progressive gait training appeared to substantially benefit an 80-year-old patient’s physical function and contribute to his potential for independent living in the community. Future studies should be conducted to further examine optimal interventions for patients with overlapping conditions such as CMT and MI.

Acknowledgements

Special thanks to Kirsten Buchanan, PhD, PT, ATC for career goal and poster conceptualization. Additional thanks to the patient for participation in this case report and to Betty Ross, DPT for supervision and assistance as Clinical Instructor.
