Functional Training to Reduce Fall Risk in a Patient Following Cancer Treatment: A Case Report
Kristin O’Kelly, BS, DPT Student
University of New England, Department of Physical Therapy

Background

- The National Cancer Institute reports that 39.6% of men and women will be diagnosed with some form of cancer during their lifetime.
- Studies have demonstrated that over half of cancer survivors age 55 and over have fallen in the past year, possibly as a result of treatment and subsequent muscle weakness, difficulty with balance, and impaired walking.1
- Multiple studies have looked at the long term effects of cancer treatment and survivorship, but few studies look at interventions to combat decline in function.
- Purpose of this case report was to report the interventions utilized in the treatment of an individual post-cancer treatment, with the intention of decreasing future fall risk by addressing three modifiable factors: muscle weakness, balance impairment, and walking difficulty.2

Patient History

- A 76-year-old female referred to skilled nursing facility (SNF) with decreased functional mobility and a medical diagnosis of nausea, vomiting, and diarrhea secondary to radiation enteritis.
- One year ago, the patient was diagnosed stage II endometriod adenocarcinoma and underwent total abdominal hysterectomy, bilateral salpingo-oophorectomy, and bilateral pelvic lymph node dissection as well as radiation for treatment.
- Past year of poor health (shingles, DVT, gastrointestinal bleeding, falls) resulting in prolonged periods of immobility.
- Participated in a total of 12 days of skilled PT services, for an hour each day, to address limitations in strength, balance, and aerobic capacity.
- Functional mobility and fall risk were assessed via six-minute walk test (6-MWT) and Berg balance scale (BBS).

Impairments

- Cardiovascular System: Following 30ft ambulation, HR increased to 102 bpm, pt became SOB, edema present at bilateral ankles (2+ to 3+).
- Integumentary System: bruising at R antecubital space.
- Neuromuscular System: balance impairment.
- Musculoskeletal System: bilateral LE gross strength impairment, gait impaired secondary to LE strength, balance and CV endurance impairments.

Interventions

<table>
<thead>
<tr>
<th>Intervention</th>
<th>Rx Week One</th>
<th>Rx Week Two</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gait Training</td>
<td>RW and CGA</td>
<td>4W and distant supervision</td>
</tr>
<tr>
<td>Transfer Training</td>
<td>Min assist x 1</td>
<td>Distant supervision</td>
</tr>
<tr>
<td>Stair Training</td>
<td>Not addressed</td>
<td>B/L UE support, CGA</td>
</tr>
</tbody>
</table>

Key: RW = walking; CGA = contract guard assist; 4W = four wheeled walker; id/wt = identity, weight

Discussion

Multiple studies have been completed that demonstrate the long lasting effects of cancer treatment on functional mobility, especially fall risk, but few demonstrate ways to mitigate the decline. According to a study by Huang et al3, muscle weakness and difficulty with balance and walking have been linked to increased falls in cancer survivors. With the interventions provided, the patient showed improvements in functional mobility, balance and lower extremity strength, as well as improved cardiovascular endurance and fall risk as assessed by the 6-MWT and BBS respectively.
