Shoulder Strengthening, Taping and Postural Reeducation in a Breast Cancer Survivor after Bilateral Mastectomy: A Case Report

Nalis Mbianda, Doctor of Physical Therapy Student, University of New England, Department of Physical Therapy, Portland, ME

Background and Purpose
- Breast cancer is the most common cancer experienced by females in the United States.¹
- In breast cancer survivors, weakness of the rotator cuff musculature is often considered a contributing factor to rotator cuff pathology.²
- The purpose of this case report was to help fill the gaps in literature by documenting the use of therapeutic exercises to strengthen the shoulder complex, in conjunction with taping techniques for postural reeducation, of a female breast cancer survivor.

Case Description
- 56-year-old Caucasian female
- Diagnosed with invasive ductal right (R) breast cancer. Neoadjuvant chemotherapy initiated immediately following diagnosis.
- Bilateral mastectomy performed four months later, with - R sentinel lymph node biopsy (0/4).
- The patient was seen by an occupational therapist (OT) one month after surgery for the treatment of axillary web syndrome and lymphedema in the R axilla for four weeks.
- She discontinued OT at the start of PT for the diagnosis of R shoulder impingement.
- Problem list: R shoulder weakness, pain, poor posture, and extreme fatigue with upper extremity activities.

Interventions

Manual Therapy
- Subscapularis trigger point release
- Scapulothoracic spine posterior and anterior glide mobilization in sitting

McConnell Taping
- McConnell taping sequence: A. Prior to taping, B. Mid taping, C. End result

Therapeutic Exercise
- Therapeutic exercises: A. Rows, B. Standing "Y", C. Bilateral external rotation in sitting

Home Exercise Program
- Figure 1. McConnell taping sequence: A. Prior to taping, B. Mid taping, C. End result
- Figure 2. Manual Therapy: A. Subscapularis trigger point release, B. Starting position of scapulothoracic spine posterior and anterior glide mobilization in sitting, C. End position of scapulothoracic spine mobilization

Discussion
- Shoulder impingement and weakness can lead to debilitating physical impairments that may limit an individual's functional ability as well as their independence.
- Factors that positively influenced this patient's outcomes included family support, the therapeutic interventions prescribed, and high motivation.
- These findings suggest that the use of therapeutic exercises to strengthen the shoulder complex, in conjunction with taping techniques for postural reeducation, may have improved physical function through improved shoulder strength, improved postural alignment, and decreased pain with activity.
- Research is needed to validate the outcomes of combined rehabilitative techniques in breast cancer survivor with rotator cuff pathology.

Acknowledgements
The author acknowledges Amy J. Litterini, PT, DPT, for assistance with case report conceptualization, Jennifer A. Daggett, PT, for assistance with patient treatment, and the patient for her participation in this case report.
